## DYNAMO-HIA: what does it do?

- Organizes and stores necessary input data sets  
→ REFERENCE DATA
- Projects how changes in risk factor distribution affect disease-specific and summary measures of population health  
→ SIMULATION

User should tell the program how a policy affect risk factor exposure

## SIMULATION in DYNAMO: how does it work?

- Situation with current risk factor exposure : Business-as-usual or reference scenario  
= **reference scenario**:  
initial exposure + future transitions
  - Situation with changed risk factor exposure  
= **intervention scenario**  
- new initial exposure and/or future transitions
- ➔ Project future situation under both scenarios and compare
- Compare both situations: gives effect of policy, action or intervention
    - > Disease-specific measures
    - > Summary measure of population health

## How does the projection work?

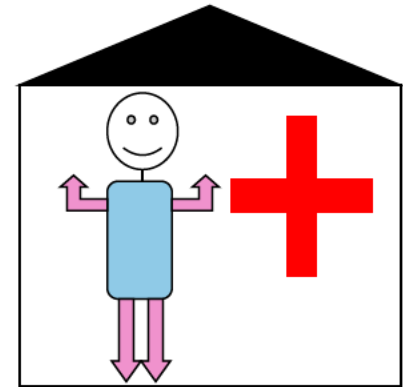

- Standard causal pathway in epidemiology

- Markov modeling framework
  - Explicit risk factor states = follows persons with a particular risk factor level development
  - Disease states: incidence, prevalence, mortality (no recovery)
  - Competing risks are taken into account
- Technical realization
  - Dynamic micro simulation (risk factor)
  - Discrete time frame using a multi state model (disease process)

Population averages

$I_{HD}$ =Incidence from Healthy to Diseased (minus Remission when specified)

$\mu_{OC}$ =Other Cause Mortality, i.e. non-diseases and relative risk of one  
 $\mu_{EM}$ =Excess Mortality, i.e. mortality due to diseases state

$RR_{Overweight}^{OC}$ =Relative Risk for incidence given overweight compared with normal weight  
 $RR_{Obese}^{OC}$ =Relative Risk for incidence given obesity compared with normal weight

$RR_{Overweight}^{OC}$ = Relative Risk for other cause mortality given overweight compared with normal weight  
 $RR_{Obese}^{OC}$ = Relative Risk for other cause mortality given Obesity compared with normal weight

## REFERENCE DATA in DYNAMO

= **INPUT for the model**

DYNAMO-HIA back-calculates from population-based data

→ Disease data can be used for all risk factors

Data-base storage is part of DYNAMO

Data on disease / risk factor must be complete before they can be used in simulation

- Risk factor exposure types:
  - **Categorical:** never, current, former smokers
  - **Continuous:** mean BMI
  - **Compound:** former smokers by time since quitting
  
- Diseases: 3 types of disease processes
  - Chronic disease
  - Partly acute **fatal** disease
  - Disease with **cured** fraction

← Combination not allowed
  
- Transitions between risk factor states: = **define the future**
  - Zero transitions = no change of individuals
  - Net transitions = keeps age-specific distribution constant
  - User-defined transitions

## SCENARIO DEFINITION

DYNAMIC MODEL: → need to define the future

- Zero transitions = no change of individuals → cohort effect
- Net transitions = keeps age-specific distribution constant  
Also: changes in initial prevalence are retained → no cohort effect

- User-defined transitions

Now, let's see how it works

## Exercise 3: running of predefined case

Predefined case= domestic falls in older persons

- Reference scenario:
  - ✓ Risk factor = percentage of barrier-free housing: 1% (same all ages)  
+ zero-transitions
  - ✓ Population = any country
  - ✓ Diseases = hip fractures
  - ✓ Fractures as disease type with acute but no chronic mortality
  - ✓ →zero excess mortality
  - ✓ →fatal fraction from CBS
  - ✓ RR barrier-free housing on fractures = 0.5
  - ✓ Incidence = hospital admission: ignores second fractures
  - ✓ Prevalence = calculated from incidence and mortality
  
- Intervention scenario:
  - ✓ Baseline prevalence of housing changed to 100%
  - ✓ zero transition rates
